

Package: mixlm (via r-universe)

November 6, 2024

Type Package

Title Mixed Model ANOVA and Statistics for Education

Version 1.4.0

Date 2024-10-07

Maintainer Kristian Hovde Liland <kristian.liland@nmbu.no>

Encoding UTF-8

Description The main functions perform mixed models analysis by least squares or REML by adding the function r() to formulas of lm() and glm(). A collection of text-book statistics for higher education is also included, e.g. modifications of the functions lm(), glm() and associated summaries from the package 'stats'.

Anova.lmm	<i>Analysis of variance with SS type II or III (including mixed models).</i>
-----------	--

Description

Replacement for Anova.lm in package car. This version adds support for random effects when needed.

Usage

```
## S3 method for class 'lmm'
Anova(mod, ...)
```

Arguments

mod	lm, aov, glm, multinom, polr, mlm, coxph, lme, mer, svyglm or other suitable model object.
...	do not use.

Value

Returns appropriate analysis of variance or halts if unsupported input is detected.

Author(s)

John Fox <jfox@mcmaster.ca>. Extended by Kristian Hovde Liland.

See Also

[Anova](#), [print.AnovaMix](#), [AnovaMix](#), [lm](#)

Examples

```
dataset <- data.frame(y = rnorm(8),
  x = factor(c(rep(1,4),rep(0,4))),
  z = factor(rep(c(1,0),4)))
mixlm <- lm(y~x*r(z),
  data = dataset)
Anova(mixlm, type="III")
```

anova.lmm

Analysis of variance (sequential SS)

Description

Wrapper for `anova.lm` in package `stats` that halts execution if unsupported input is detected.

Usage

```
## S3 method for class 'lmm'
anova(object, ...)
```

Arguments

`object` object fitted by `lm`, `lmer` or similar.
`...` possible additional argument to underlying functions.

Value

Returns appropriate analysis of variance or halts if unsupported input is detected.

Author(s)

Kristian Hovde Liland

See Also

[lm](#)

Examples

```
mixlm <- lm(y~x*r(z),
  data = data.frame(y = rnorm(8),
    x = factor(c(rep(1,4),rep(0,4))),
    z = factor(rep(c(1,0),4)))
anova(mixlm)
```

AnovaMix

Mixed model least squares analysis of variance (mixed ANOVA).

Description

Uses output from `lm()` in `mixlm` package to compute ANOVA table, variance components and errors.

Usage

```
AnovaMix(object, SStype)
```

Arguments

<code>object</code>	object fitted by <code>lm</code> (<code>mixlm</code> package) containing at least one random effect.
<code>SStype</code>	type of sums-of-squares (I/II/III) for Analysis of Variance.

Details

`AnovaMix` can either be invoked directly or through the `Anova()` function (with type III error).

Value

<code>lm</code>	linear model fitted by <code>lm</code> in package <code>mixlm</code> .
<code>anova</code>	ANOVA table.
<code>err.terms</code>	list of denominator information for F tests.
<code>denom.df</code>	numeric of denominator degrees of freedom for F tests.
<code>restricted</code>	logical indicating if ANOVA used restricted modelling.
<code>exp.mean.sq</code>	character containing expected mean squares.
<code>var.comps</code>	numeric containing variance components.
<code>random.effects</code>	character containing the random effects.
<code>ind.randoms</code>	numeric with indices of random effects in the model.
<code>formula.text</code>	character containing all effects of the model.

Note

Only balanced models are fully supported.

Author(s)

Kristian Hovde Liland

[print.AnovaMix](#), [Anova](#), [lm](#)

Examples

```
mydata <- data.frame(y = rnorm(12),
  x = factor(c(rep(2,4),rep(1,4),rep(0,4))),
  z = factor(rep(c(1,0),6)))
mixlm <- lm(y~x*r(z),
  data = mydata)
Anova(mixlm, type="III")
```

anova_reg

Analysis of variance for regression.

Description

Summarizes all effects in one.

Usage

```
anova_reg(lm.object)
```

Arguments

lm.object an object of class lm.

Value

Returns data.frame containing analysis of variance

Author(s)

Kristian Hovde Liland

Examples

```
anova_reg(lm(y~x, data=data.frame(y=1:4,x=rnorm(4))))
```

best.subsets	<i>F-test based best subset selection.</i>
--------------	--

Description

Adaptation of existing methods based on AIC/BIC.

Usage

```
best.subsets(model, nbest = 5, nvmax, digits, force.in = "NULL")
```

Arguments

model	object class <code>lm</code> to select effects from.
nbest	numeric indicating number of models to report of each size.
nvmax	numeric maximum size of subsets to examine.
digits	numeric giving number of digits in format of output.
force.in	character vector indicating effects to keep in all models.

Details

F-based versions of built in subset method.

Value

No return, only print.

Author(s)

Kristian Hovde Liland

Examples

```
data <- data.frame(y = rnorm(8),  
  x = factor(c('a', 'a', 'a', 'a', 'b', 'b', 'b', 'b'))),  
  z = factor(c('a', 'a', 'b', 'b', 'a', 'a', 'b', 'b')))  
mod <- lm(y ~ x + z, data=data)  
best.subsets(mod)
```

`CIgrandMean`*Confidence interval for the grand mean of a linear model*

Description

This function estimates the confidence interval for the grand mean of a balanced linear (mixed) model.

Usage

```
CIgrandMean(object, alpha = 0.05)
## S3 method for class 'CIgm'
print(x, ...)
```

Arguments

<code>object</code>	An <code>lm</code> object possibly containing random effects.
<code>alpha</code>	A scalar significance level for the confidence interval.
<code>x</code>	An object returned from <code>CIgrandMean</code> .
<code>...</code>	Additional arguments (not used).

Details

This implementation is only valid for models containing no continuous effects and only balanced data.

Value

`CIgrandMean` returns a vector of interval endpoints and center. `print.CIgm` has no return.

Author(s)

Kristian Hovde Liland

References

Suggestions are welcome.

Examples

```
set.seed(42)
dataset <- data.frame(y=rnorm(8), x=factor(c(rep(1,4),rep(0,4))), z=factor(rep(c(1,0),4)))
mixlm <- lm(y~x*r(z), data = dataset)
CIgrandMean(mixlm)
```

confusion	<i>Confusion matrix.</i>
-----------	--------------------------

Description

Computes the confusion matrix of a classification result.

Usage

```
confusion(true, predicted)
```

Arguments

true	true classes.
predicted	predicted classes.

Details

This is a pure print function.

Examples

```
true <- c('a','a','b','b','c','c')
predicted <- c('a','c','b','b','a','c')
confusion(true, predicted)
```

contr.weighted	<i>Contrast matrix for weighted effect coding</i>
----------------	---

Description

Weighted contrast coding for linear models.

Usage

```
contr.weighted(x, base)
```

Arguments

x	factor for which a contrast matrix should be made.
base	factor level used as basis for contrast coding. Default is the (first) level with maximum frequency.

Details

Different from the contrasts made through the `stats` package functions this contrast requires a full factor vector as input rather than its respective levels as weights are computed from the frequencies of the factor levels.

Value

A matrix with `n` rows and `n-1` values.

Note

`contr.weighted` cannot be used directly as a replacement for other contrasts by name, but must be used via contrasts matrix computations.

unbalanced <- factor(c(rep("A", 3), rep("B", 3), rep("C", 2)))
# Weighted coding when applied to balanced data
contr.weighted(balanced)
# Weighted coding when applied to unbalanced data (default base level)
contr.weighted(unbalanced)
# Weighted coding when applied to unbalanced data (base level = "C")
contr.weighted(unbalanced, "C")
```

effect.labels *Create new effect labels for lm*

Description

Alternative notation of effect labels including levels.

Usage

```
effect.labels(t, data)
```

Arguments

t	Terms object.
data	Corresponding model.matrix.

Value

names	Character vector of effect labels.
-------	------------------------------------

Author(s)

Kristian Hovde Liland

forward	<i>F-test based model effect selection for linear models.</i>
---------	---

Description

Adaptation of existing methods based on AIC/BIC.

Usage

```
forward(model, alpha = 0.2, full = FALSE, force.in)
backward(model, alpha = 0.2, full = FALSE, hierarchy = TRUE, force.in)
stepWise(model, alpha.enter = 0.15, alpha.remove = 0.15, full = FALSE)
stepWiseBack(model, alpha.remove = 0.15, alpha.enter = 0.15, full = FALSE)
wideForward(formula, data, alpha = 0.2, force.in = NULL)
```

Arguments

model	object class <code>lm</code> to select effects from.
formula	formula specifying all possible effects.
data	<code>data.frame</code> corresponding to formula.
alpha	numeric p-value cut-off for inclusion/exclusion.
full	logical indicating extended output of forward/backward selection.
force.in	character vector indicating effects to keep in all models.
alpha.enter	numeric p-value cut-off for inclusion.
alpha.remove	numeric p-value cut-off for exclusion.
hierarchy	logical indicating if hierarchy should be forced in backward selection.

Details

F-based versions of built in stepwise methods.

Value

The final linear model after selection is returned.

Author(s)

Kristian Hovde Liland

Examples

```
set.seed(0)
data <- data.frame(y = rnorm(8),
  x = factor(c('a','a','a','a','b','b','b','b')),
  z = factor(c('a','a','b','b','a','a','b','b')))
mod <- lm(y ~ x + z, data=data)
forward(mod)
backward(mod)
stepWise(mod)
stepWiseBack(mod)

# Forward selection for wide matrices (large number of predictors)
set.seed(0)
mydata <- data.frame(y = rnorm(6), X = matrix(rnorm(60),6,10))
fs <- wideForward(y ~ ., mydata)
print(fs)
```

fparse

Effects of formulas.

Description

Extracts all effects from a formula, even though inside functions or interactions.

Usage

```
fparse(f)
```

Arguments

f formula to be parsed.

Value

Returns a character vector containing all effects.

Author(s)

Bjørn-Helge Mevik

See Also[rparse](#)**Examples**

```
f <- formula(y~x*r(z))
fparse(f)
```

glm

*Fitting Generalized Linear Models***Description**

glm is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution. The version of glm supplied by the package `mixlm` parses to `glmer` for mixed modelling.

Usage

```
glm(formula, family = gaussian, data, weights, subset,
     na.action, start = NULL, etastart, mustart, offset,
     control = list(...), model = TRUE, method = "glm.fit",
     x = FALSE, y = TRUE, contrasts = NULL, REML = TRUE, ...)
```

Arguments

formula	an object of class " formula " (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.
family	a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See family for details of family functions.)
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>glm</code> is called.
weights	an optional vector of 'prior weights' to be used in the fitting process. Should be <code>NULL</code> or a numeric vector.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of options , and is <code>na.fail</code> if that is unset. The 'factory-fresh' default is <code>na.omit</code> . Another possible value is <code>NULL</code> , no action. Value <code>na.exclude</code> can be useful.
start	starting values for the parameters in the linear predictor.

etastart	starting values for the linear predictor.
mustart	starting values for the vector of means.
offset	this can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more <code>offset</code> terms can be included in the formula instead or as well, and if more than one is specified their sum is used. See <code>model.offset</code> .
control	a list of parameters for controlling the fitting process. For <code>glm.fit</code> this is passed to <code>glm.control</code> .
model	a logical value indicating whether <i>model frame</i> should be included as a component of the returned value.
method	the method to be used in fitting the model. The default method "glm.fit" uses iteratively reweighted least squares (IWLS): the alternative "model.frame" returns the model frame and does no fitting. User-supplied fitting functions can be supplied either as a function or a character string naming a function, with a function which takes the same arguments as <code>glm.fit</code> . If specified as a character string it is looked up from within the stats namespace.
x, y	For <code>glm</code> : logical values indicating whether the response vector and model matrix used in the fitting process should be returned as components of the returned value. For <code>glm.fit</code> : <code>x</code> is a design matrix of dimension $n * p$, and <code>y</code> is a vector of observations of length <code>n</code> .
contrasts	an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .
REML	is used to invoke restricted maximum likelihood (TRUE) or maximum likelihood (FALSE) estimation instead of least squares.
...	For <code>glm</code> : arguments to be used to form the default <code>control</code> argument if it is not supplied directly. For <code>weights</code> : further arguments passed to or from other methods.

Details

A typical predictor has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for response. For binomial and quasibinomial families the response can also be specified as a `factor` (when the first level denotes failure and all others success) or as a two-column matrix with the columns giving the numbers of successes and failures. A terms specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with any duplicates removed.

A specification of the form `first:second` indicates the the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the *cross* of `first` and `second`. This is the same as `first + second + first:second`.

The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a terms object as the formula.

Non-NULL `weights` can be used to indicate that different observations have different dispersions (with the values in `weights` being inversely proportional to the dispersions); or equivalently, when

the elements of weights are positive integers w_i , that each response y_i is the mean of w_i unit-weight observations. For a binomial GLM prior weights are used to give the number of trials when the response is the proportion of successes: they would rarely be used for a Poisson GLM.

`glm.fit` is the workhorse function: it is not normally called directly but can be more efficient where the response vector and design matrix have already been calculated.

If more than one of `etastart`, `start` and `mustart` is specified, the first in the list will be used. It is often advisable to supply starting values for a `quasi` family, and also for families with unusual links such as `gaussian("log")`.

All of `weights`, `subset`, `offset`, `etastart` and `mustart` are evaluated in the same way as variables in `formula`, that is first in data and then in the environment of `formula`.

For the background to warning messages about ‘fitted probabilities numerically 0 or 1 occurred’ for binomial GLMs, see Venables & Ripley (2002, pp. 197–8).

Value

`glm` returns an object of class inheriting from `"glm"` which inherits from the class `"lm"`. See later in this section. If a non-standard method is used, the object will also inherit from the class (if any) returned by that function.

The function `summary` (i.e., `summary.glm`) can be used to obtain or print a summary of the results and the function `anova` (i.e., `anova.glm`) to produce an analysis of variance table.

The generic accessor functions `coefficients`, `effects`, `fitted.values` and `residuals` can be used to extract various useful features of the value returned by `glm`.

`weights` extracts a vector of weights, one for each case in the fit (after subsetting and `na.action`).

An object of class `"glm"` is a list containing at least the following components:

<code>coefficients</code>	a named vector of coefficients
<code>residuals</code>	the <i>working</i> residuals, that is the residuals in the final iteration of the IWLS fit. Since cases with zero weights are omitted, their working residuals are NA.
<code>fitted.values</code>	the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.
<code>rank</code>	the numeric rank of the fitted linear model.
<code>family</code>	the <code>family</code> object used.
<code>linear.predictors</code>	the linear fit on link scale.
<code>deviance</code>	up to a constant, minus twice the maximized log-likelihood. Where sensible, the constant is chosen so that a saturated model has deviance zero.
<code>aic</code>	A version of Akaike’s <i>An Information Criterion</i> , minus twice the maximized log-likelihood plus twice the number of parameters, computed by the <code>aic</code> component of the family. For binomial and Poisson families the dispersion is fixed at one and the number of parameters is the number of coefficients. For gaussian, Gamma and inverse gaussian families the dispersion is estimated from the residual deviance, and the number of parameters is the number of coefficients plus one. For a gaussian family the MLE of the dispersion is used so this is a valid value of AIC, but for Gamma and inverse gaussian families it is not. For families fitted by quasi-likelihood the value is NA.

<code>null.deviance</code>	The deviance for the null model, comparable with <code>deviance</code> . The null model will include the offset, and an intercept if there is one in the model. Note that this will be incorrect if the link function depends on the data other than through the fitted mean: specify a zero offset to force a correct calculation.
<code>iter</code>	the number of iterations of IWLS used.
<code>weights</code>	the <i>working</i> weights, that is the weights in the final iteration of the IWLS fit.
<code>prior.weights</code>	the weights initially supplied, a vector of 1s if none were.
<code>df.residual</code>	the residual degrees of freedom.
<code>df.null</code>	the residual degrees of freedom for the null model.
<code>y</code>	if requested (the default) the y vector used. (It is a vector even for a binomial model.)
<code>x</code>	if requested, the model matrix.
<code>model</code>	if requested (the default), the model frame.
<code>converged</code>	logical. Was the IWLS algorithm judged to have converged?
<code>boundary</code>	logical. Is the fitted value on the boundary of the attainable values?
<code>call</code>	the matched call.
<code>formula</code>	the formula supplied.
<code>terms</code>	the <code>terms</code> object used.
<code>data</code>	the data argument.
<code>offset</code>	the offset vector used.
<code>control</code>	the value of the <code>control</code> argument used.
<code>method</code>	the name of the fitter function used, currently always <code>"glm.fit"</code> .
<code>contrasts</code>	(where relevant) the contrasts used.
<code>xlevels</code>	(where relevant) a record of the levels of the factors used in fitting.
<code>na.action</code>	(where relevant) information returned by <code>model.frame</code> on the special handling of NAs.

In addition, non-empty fits will have components `qr`, `R` and `effects` relating to the final weighted linear fit.

Objects of class `"glm"` are normally of class `c("glm", "lm")`, that is inherit from class `"lm"`, and well-designed methods for class `"lm"` will be applied to the weighted linear model at the final iteration of IWLS. However, care is needed, as extractor functions for class `"glm"` such as `residuals` and `weights` do **not** just pick out the component of the fit with the same name.

If a `binomial` `glm` model was specified by giving a two-column response, the weights returned by `prior.weights` are the total numbers of cases (factored by the supplied case weights) and the component `y` of the result is the proportion of successes.

Fitting functions

The argument `method` serves two purposes. One is to allow the model frame to be recreated with no fitting. The other is to allow the default fitting function `glm.fit` to be replaced by a function which takes the same arguments and uses a different fitting algorithm. If `glm.fit` is supplied as a character string it is used to search for a function of that name, starting in the `stats` namespace.

The class of the object return by the fitter (if any) will be prepended to the class returned by `glm`.

Author(s)

The original R implementation of `glm` was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the R Core team.

The design was inspired by the S function of the same name described in Hastie & Pregibon (1992).

Mixed model additions by Kristian Hovde Liland.

hasseMod

Hasse Diagram from Linear Model

Description

This function extracts terms from a linear model object and creates a Hasse diagram of the terms. The function is useful for visualizing the structure of a linear model. If the model contains random effects, these are placed in parentheses in the diagram. Manually placed terms are supported to some extent, see example for usage.

Usage

```
hasseMod(object, manualTerms=NULL, manualParents=NULL,
         meanName="M", errorName="(E)")
```

Arguments

object	A linear model object, e.g., lm .
manualTerms	A vector of terms that should be placed manually in the diagram.
manualParents	A list of vectors with the parents of the terms in manualTerms.
meanName	The name of the mean term (default = "M").
errorName	The name of the error term (default = "(E)").

Value

A list with the levels of the diagram and the adjacency matrix.

  data = data.frame(y = rnorm(8),
    x = factor(c(rep(1,4),rep(0,4))),
    z = factor(rep(c(1,0),4)))
  is.balanced(mixlm)
```

Description

lm is used to fit linear models. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although [aov](#) may provide a more convenient interface for these). The version distributed through the package `mixlm` extends the capabilities with balanced mixture models and `lmer` interfacing. Random effects are indicated by wrapping their formula entries in `r()`. Also, effect level names are kept in printing.

Usage

```
lm(formula, data, subset, weights, na.action,
  method = "qr", model = TRUE, x = TRUE, y = TRUE, qr = TRUE,
  singular.ok = TRUE, contrasts = "contr.sum", offset,
  unrestricted = TRUE, REML = NULL, ...)
```

Arguments

- | | |
|---------|--|
| formula | an object of class " <code>formula</code> " (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under ‘Details’. |
| data | an optional data frame, list or environment (or object coercible by <code>as.data.frame</code> to a data frame) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>lm</code> is called. |
| subset | an optional vector specifying a subset of observations to be used in the fitting process. |
| weights | an optional vector of weights to be used in the fitting process. Should be <code>NULL</code> or a numeric vector. If non- <code>NULL</code> , weighted least squares is used with weights <code>weights</code> (that is, minimizing $\sum(w \cdot e^2)$); otherwise ordinary least squares is used. See also ‘Details’. |

<code>na.action</code>	a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> . Another possible value is <code>NULL</code> , no action. Value <code>na.exclude</code> can be useful.
<code>method</code>	the method to be used; for fitting, currently only <code>method = "qr"</code> is supported; <code>method = "model.frame"</code> returns the model frame (the same as with <code>model = TRUE</code> , see below).
<code>model, x, y, qr</code>	logicals. If <code>TRUE</code> the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.
<code>singular.ok</code>	logical. If <code>FALSE</code> (the default in S but not in R) a singular fit is an error.
<code>contrasts</code>	character indicating which coding should be applied to all factors or an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> . Defaults to <code>"contr.sum"</code> . See Details for more information.
<code>offset</code>	this can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting. This should be <code>NULL</code> or a numeric vector of length equal to the number of cases. One or more <code>offset</code> terms can be included in the formula instead or as well, and if more than one are specified their sum is used. See <code>model.offset</code> .
<code>unrestricted</code>	additional argument for switching between unrestricted and restricted models if including random variables.
<code>REML</code>	is used to invoke restricted maximum likelihood (<code>TRUE</code>) or maximum likelihood (<code>FALSE</code>) estimation instead of least squares.
<code>...</code>	additional arguments to be passed to the low level regression fitting functions (see below).

Details

Models for `lm` are specified symbolically. A typical model has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for response. A terms specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with duplicates removed. A specification of the form `first:second` indicates the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the *cross* of `first` and `second`. This is the same as `first + second + first:second`.

If the formula includes an `offset`, this is evaluated and subtracted from the response.

If `response` is a matrix a linear model is fitted separately by least-squares to each column of the matrix.

See `model.matrix` for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a terms object as the formula (see `avov` and `demo(glm.vr)` for an example).

A formula has an implied intercept term. To remove this use either `y ~ x - 1` or `y ~ 0 + x`. See `formula` for more details of allowed formulae.

Non-`NULL` weights can be used to indicate that different observations have different variances (with the values in `weights` being inversely proportional to the variances); or equivalently, when the elements of `weights` are positive integers w_i , that each response y_i is the mean of w_i unit-weight

observations (including the case that there are w_i observations equal to y_i and the data have been summarized).

lm calls the lower level functions `lm.fit`, etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of weights, subset and offset are evaluated in the same way as variables in formula, that is first in data and then in the environment of formula.

The contrasts argument is applied when the lm model is fitted. In addition to the standard contrasts from the stats package, one can choose weighted coding: `contr.weighted` which balances unbalanced data through factor weighting. Different from the original version of lm, a single contrast can be indicated to automatically be applied to all factors.

Value

lm returns an object of class `c("lmm", "lm")` or for multiple responses of class `c("mlm", "lm")`.

The functions `summary` and `anova` are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions `coefficients`, `effects`, `fitted.values` and `residuals` extract various useful features of the value returned by lm.

An object of class "lm" is a list containing at least the following components:

<code>coefficients</code>	a named vector of coefficients
<code>residuals</code>	the residuals, that is response minus fitted values.
<code>fitted.values</code>	the fitted mean values.
<code>rank</code>	the numeric rank of the fitted linear model.
<code>weights</code>	(only for weighted fits) the specified weights.
<code>df.residual</code>	the residual degrees of freedom.
<code>call</code>	the matched call.
<code>terms</code>	the <code>terms</code> object used.
<code>contrasts</code>	(only where relevant) the contrasts used.
<code>xlevels</code>	(only where relevant) a record of the levels of the factors used in fitting.
<code>offset</code>	the offset used (missing if none were used).
<code>y</code>	if requested, the response used.
<code>x</code>	if requested, the model matrix used.
<code>model</code>	if requested (the default), the model frame used.
<code>na.action</code>	(where relevant) information returned by <code>model.frame</code> on the special handling of NAs.

In addition, non-null fits will have components `assign`, `effects` and (unless not requested) `qr` relating to the linear fit, for use by extractor functions such as `summary` and `effects`.

And models containing random effect will contain `random` having additional information about the model.

Using time series

Considerable care is needed when using `lm` with time series.

Unless `na.action = NULL`, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting NAs would invalidate the time series attributes, and if NAs are omitted in the middle of the series the result would no longer be a regular time series.)

Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by `ts.intersect(..., dframe = TRUE)`, then apply a suitable `na.action` to that data frame and call `lm` with `na.action = NULL` so that residuals and fitted values are time series.

Note

Offsets specified by `offset` will not be included in predictions by `predict.lm`, whereas those specified by an offset term in the formula will be.

Author(s)

The design was inspired by the S function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973). Mixed model extensions by Kristian Hovde Liland.

```

plotprops

Property plots for relevant component analysis

Description

Plot summary of relevant component analysis.

Usage

```
plotprops(Y, X, doscaleX = FALSE, docenterX = TRUE, ncomp, subset)
```

Arguments

Y	Response matrix.
X	Predictor matrix.
doscaleX	Standardize predictors.
docenterX	Center predictors.
ncomp	Number of singular values and eigenvalues to extract.
subset	Subset of predictor and response.

Value

Only plotting.

X <- matrix(rnorm(100),20,5)
Y <- matrix(rnorm(20),20,1)
plotprops(Y, X, doscaleX = FALSE, docenterX = TRUE, 5)
```

PRESS

Prediction fits

Description

Various summaries of predictions and PRESS residuals.

Usage

```
R2pred(object = NULL)
RMSEP(object)
rmsep(object)
PRESS(object = NULL)
PRESS.res(object = NULL, ncomp = NULL)
PRESS.pred(object = NULL, ncomp = NULL)
```

Arguments

`object` a fitted model of type `lm` or `mvr`.
`ncomp` number of components to use with `mvr` (optional).

Details

Predictions are extracted and summaries/residuals are computed.

Value

Returns either an object of summaries or residuals.

Author(s)

Kristian Hovde Liland

Examples

```
data <- data.frame(y = rnorm(8),
  x = factor(c('a','a','a','a','b','b','b','b')),
  z = factor(c('a','a','b','b','a','a','b','b')))
mod <- lm(y ~ x + z, data=data)
RMSEP(mod)
rmsep(mod) # Alias to distinguish it from pls::RMSEP
R2pred(mod)
PRESS(mod)
PRESS.res(mod)
PRESS.pred(mod)
```

```
print.AnovaMix          Print method for objects of class(AnovaMix)
```

Description

Prints relevant information like the ANOVA table, variance components and errors.

Usage

```
## S3 method for class 'AnovaMix'
print(x, ...)
```

Arguments

```
x          AnovaMix object to be printed.
...        Additional arguments (not supported yet).
```

Note

Only balanced models are fully supported.

mixlm <- lm(y~x*r(z),
  data = data.frame(y = rnorm(8),
    x = factor(c(rep(1,4),rep(0,4))),
    z = factor(rep(c(1,0),4))))
Anova(mixlm,type="III")
```

 print.summary.lmm *Summarizing Linear Model Fits*

Description

summary method for class "lmm".

Usage

```
## S3 method for class 'summary.lmm'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

x	an object of class "summary.lmm", usually, a result of a call to summary.lmm.
digits	the number of significant digits to use when printing.
symbolic.cor	logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.
signif.stars	logical. If TRUE, 'significance stars' are printed for each coefficient.
...	further arguments passed to or from other methods.

Details

This adaptation of print.summary.lm from package stats slightly alters the output to better conform with text-book notation.

print.summary.lm tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if signif.stars is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)\$correlation directly.

Value

The function summary.lm computes and returns a list of summary statistics of the fitted linear model given in object, using the components (list elements) "call" and "terms" from its argument, plus

residuals	the <i>weighted</i> residuals, the usual residuals rescaled by the square root of the weights specified in the call to lm.
coefficients	a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted.
aliased	named logical vector showing if the original coefficients are aliased.

sigma the square root of the estimated variance of the random error

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i w_i R_i^2,$$

where R_i is the i -th residual, residuals[i].

df degrees of freedom, a 3-vector $(p, n-p, p^*)$, the last being the number of non-aliased coefficients.

fstatistic (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.

r.squared R^2 , the 'fraction of variance explained by the model',

$$R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i (y_i - y^*)^2},$$

where y^* is the mean of y_i if there is an intercept and zero otherwise.

adj.r.squared the above R^2 statistic 'adjusted', penalizing for higher p .

cov.unscaled a $p \times p$ matrix of (unscaled) covariances of the $\hat{\beta}_j, j = 1, \dots, p$.

correlation the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified.

symbolic.cor (only if correlation is true.) The value of the argument symbolic.cor.

na.action from object, if present there.

trt <- c(4.81,4.17,4.41,3.59,5.87,3.83,6.03,4.89,4.32,4.69)
group <- gl(2,10,20, labels=c("Ctl","Trt"))
weight <- c(ctl, trt)
sld90 <- summary(lm.D90 <- lm(weight ~ group -1))# omitting intercept
sld90
```

prop.test.ordinary *Test of Equal or Given Proportions in text-book version*

Description

This adaptation of prop.test from package stats strips the test down to a text-book version.

prop.test can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

Usage

```
prop.test.ordinary(x, n, p = NULL,
                  alternative = c("two.sided", "less", "greater"),
                  conf.level = 0.95, correct = TRUE, pooled = TRUE)
```

Arguments

<code>x</code>	a vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.
<code>n</code>	a vector of counts of trials; ignored if <code>x</code> is a matrix or a table.
<code>p</code>	a vector of probabilities of success. The length of <code>p</code> must be the same as the number of groups specified by <code>x</code> , and its elements must be greater than 0 and less than 1.
<code>alternative</code>	a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.
<code>conf.level</code>	confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.
<code>correct</code>	a logical indicating whether Yates' continuity correction should be applied where possible.
<code>pooled</code>	a logical indicating wheter pooled standard deviation should be used..

Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If `p` is `NULL` and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by `alternative`. A confidence interval for the difference of proportions with confidence level as specified by `conf.level` and clipped to $[-1, 1]$ is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is `NULL`, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is `p`, or .5 if `p` is not given. The alternative is that the probability of success is less than, not equal to, or greater than `p` or 0.5, respectively, as specified by `alternative`. A confidence interval for the underlying proportion with confidence level as specified by `conf.level` and clipped to $[0, 1]$ is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test.

Finally, if `p` is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by `p`. The alternative is always "two.sided", the returned confidence interval is `NULL`, and continuity correction is never used.

Value

A list with class "htest" containing the following components:

statistic	the value of Pearson's chi-squared test statistic.
parameter	the degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value	the p-value of the test.
estimate	a vector with the sample proportions x/n .
conf.int	a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and p is not given, or NULL otherwise. In the cases where it is not NULL, the returned confidence interval has an asymptotic confidence level as specified by <code>conf.level</code> , and is appropriate to the specified alternative hypothesis.
null.value	the value of p if specified by the null, or NULL otherwise.
alternative	a character string describing the alternative.
method	a character string indicating the method used, and whether Yates' continuity correction was applied.
data.name	a character string giving the names of the data.

rparse *Removes function r() from formulas.*

Description

Removes function r() from formulas. Can also convert to lmer formula.

Usage

```
rparse(f, REML = FALSE)
```

Arguments

f formula to be stripped of r().
REML logical indicating if lmer conversion should be done.

Value

Formula without r(), possibly converted to lmer mixed model format.

f <- formula(y~x*r(z))  
rparse(f)
```

simple.glht *Pairwise comparison with multiple testing compensation.*

Description

Extension of glht from the multcomp package to handle Fisher family-wise error and Bonferroni testing. Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey's 'Honest Significant Difference' method, Fisher's family-wise error, or Bonferroni testing.

Usage

```
simple.glht(mod, effect, corr = c("Tukey", "Bonferroni", "Fisher"),
  level = 0.95, df = NULL, ...)
```

Arguments

mod	A fitted model object, usually an <code>lm</code> or <code>glm</code> fit.
effect	A character vector giving the term of the fitted model for which the intervals should be calculated. This can also be an interaction.
corr	A character vector giving the multiple testing correction method. Defaults to Tukey.
level	A numeric value between zero and one giving the family-wise confidence level to use.
df	User supplied number of degrees of freedom. If not supplied or NULL, the default is to extract these from the model.
...	Optional additional arguments. None are used at present.

Details

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If which specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

Value

An object of classes "simple.glht", "summary.glht" and "glht" containing information to produce confidence intervals, tests and plotting.

There are `print`, `plot` and `cld` methods for class "simple.glht". The `plot` method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

t_test	<i>Text book versions of t-tests and z-tests.</i>
--------	---

Description

Adaptations of base t.test to better conform to text book standards. t_test_sum and z_test_sum takes summarized data as input.

Usage

```
t_test(x, ...)  
z_test(x, ...)
```

```
## Default S3 method:
```

```
t_test(x, y = NULL, alternative = c("two.sided", "less", "greater"),  
      mu = 0, paired = FALSE, var.equal = FALSE, conf.level = 0.95, ...)
```

```
## Default S3 method:
```

```
z_test(x, y = NULL, alternative = c("two.sided", "less", "greater"),  
      mu = 0, paired = FALSE, var.equal = FALSE, conf.level = 0.95, sds = NULL, ...)
```

```
## S3 method for class 'formula'
t_test(formula, data, subset, na.action, ...)
## S3 method for class 'formula'
z_test(formula, data, subset, na.action, ...)

## Function for summarized data:
t_test_sum(means, sds, ns, alternative = c("two.sided", "less", "greater"),
  mu = 0, var.equal = FALSE, conf.level = 0.95, z.test = FALSE, ...)
z_test_sum(means, sds, ns, alternative = c("two.sided", "less", "greater"),
  mu = 0, var.equal = FALSE, conf.level = 0.95, z.test = TRUE, ...)
```

Arguments

x	a (non-empty) numeric vector of data values.
y	an optional (non-empty) numeric vector of data values.
alternative	a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
mu	a number indicating the true value of the mean (or difference in means if you are performing a two sample test).
paired	a logical indicating whether you want a paired t-test.
var.equal	a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.
conf.level	confidence level of the interval.
formula	a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> .
subset	an optional vector specifying a subset of observations to be used.
na.action	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
means	means of groups.
sds	standard deviations of groups.
ns	number of objects in groups.
z.test	normal approximation.
...	further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

`alternative = "greater"` is the alternative that x has a larger mean than y.

If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are silently removed (in pairs if paired is TRUE). If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

Value

A list with class "htest" containing the following components:

statistic	the value of the t-statistic.
parameter	the degrees of freedom for the t-statistic.
p.value	the p-value for the test.
conf.int	a confidence interval for the mean appropriate to the specified alternative hypothesis.
estimate	the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.
null.value	the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
alternative	a character string describing the alternative hypothesis.
method	a character string indicating what type of t-test was performed.
data.name	a character string giving the name(s) of the data.

Examples

```
t.test(1:10,y=c(7:20))      # P = .00001855
t.test(1:10,y=c(7:20, 200)) # P = .1245    -- NOT significant anymore

## Classical example: Student's sleep data
plot(extra ~ group, data = sleep)
## Traditional interface
with(sleep, t.test(extra[group == 1], extra[group == 2]))
## Formula interface
t_test(extra ~ group, data = sleep)
```
